Chapter 1. Developing pods

Use this information to develop Cúram pods. Pods are presented through a standard UIM Page. The UIM includes the PodContainer.vim that contains the predefined API for interacting with the pod. The PodContainer interface allows the client to interact with the server. A PodLoader is required for each pod.

Overview

The guide is a cookbook for Developers who want to create Pods. The guide coaches Developers through various scenarios beginning with the simplest implementation of a Pod, then adding content to Pods using tools provided and eventually introducing more advanced scenarios where the user requires knowledge of the widget development process.

The guide is aimed at Developers who want to create new Pods and new Pod Pages.

Prerequisites

Users of this guide need basic Java™, XML, HTML and CSS skills and a knowledge of the development environment. For the more advanced material the user needs to be familiar with the rendering framework which is covered in the Cúram Widget Development Guide.

Cúram Personal Page Configuration Guide	How to configure Personal Pages (Pod Pages)

A Technical Overview

What is a Pod?

A Pod is a user interface widget that can be placed on a client page. In this respect, it is no different to any other user interface widget that presents data such as a list or cluster. Where a Pod differs from other types of widgets is that it can be placed in a Pod-Container where a number of more features are activated, such as the ability to be repositioned in the container and the persistence of user settings such as whether the Pod is displayed and what filter settings are applied. A filter is an optional feature of a Pod that allows the content to be customized by the user, it can be accessed if available through the pen icon on the title bar of the Pod.

What is a Pod page?

A Pod page is a UIM page, which contains a Pod-Container widget. The Pod-Container widget manages Pods. The widget is configured to present a selection of Pods that can be viewed in the container. The addition and removal of Pods from the container is managed through a *customization-console*. The Pod-Container widget manages the movement of Pods to different locations within the container. Where applicable it processes filters associated with Pods. In each case, the last configuration of the Page is saved for the current user and retrieved the next time that they load the page.

How does it work?

The next section provides an overview of the artifacts that work together to present a Pod page.

UIM Page

The Pods are presented through a standard UIM Page. The UIM must include the `PodContainer.vim` which contains the predefined API for interacting with the Pods infrastructure including the display of the page and saving of user preferences.

PodContainer

The PodContainer is the interface through which the client interacts with the server. At the display phase, the server interface invokes the `loadData()` method on the PodContainer class. At action phase 1 of the save APIs processes the data from the Pod-Container. The `PodContainer.vim` provides a reusable interface to the Pod infrastructure, add the `PodContainer.vim` to your UIM page and you have a fully functioning interface.

PodLoader

A PodLoader must be written for each Pod. The PodLoader defines the Pod and its content. This book mainly deals with the development of PodLoaders.

Database Tables

A number of tables are used to manage Pods.

Table 2. Database tables used to load Pods	
Table	Description
PODTYPE	A list of all existing Pods
PODLOADERBINDINGS	A list of all existing PodLoaders mapped to a Pod type
PAGECONFIG	A list of configurations of Pod Pages
USERPAGECONFIG	A list of user customizations of Pod Pages

Loading the Page

At the display phase, the server interface starts the `loadData()` method on the PodContainer class. The PodContainer uses the PodContainerManager to identify all the Pods to be displayed on the page that uses the information in the PAGECONFIG and USERPAGECONFIG database tables. The PodContainerManager then identifies the PodLoader for each Pod to be displayed using the information in the PodType and PodLoaderBindings codetables. The PodContainer manager starts the `createPod()` method on each PodLoader. The PodLoader supplies the data for a single Pod and the PodContainerManger builds up the cumulative data for all the Pods within the container.

Rendering the page

The page rendering is handled by a collection of renderers. The rendering begins with the PodContainerRenderer, which receives the document from the loading process and generates the PodContainer widget. It then delegates the rendering of Pods to a Pod renderer, which in turn, delegates to other renderers by using markers in the data it receives. Each renderer returns its own content that it either generates itself or generates with the help of other renderers. This pattern of delegation is repeated until all content is rendered.

For details about the rendering framework and how renderers interact, see "Developing Custom Widgets".

Saving the Page

At the action phase, the server interface saves any changes that the user made to the Pod selection and layout of the container back to the database again through the PodContainer API. The page is saved by any of the following actions, clicking the save button in the customization console, clicking the save button on a Pod filter, dragging and dropping a Pod (each time a Pod is dropped the save action is invoked to record the new layout of the page).

Configuring Pods

A Pod page can be configured through an Administration wizard, which allows the layout and content of the Pod page to be defined. A full explanation of the Administration wizard is available in the Curam Personal Page Configuration guide.

Pod Dimensions

The dimensions of a Pod are not directly specified by a Pod. This allows Pods to dynamically resize to fit their environment and facilitates the reuse of Pods across Pod containers.

Pod Height

The height of each Pod is determined by its content. A Pod's height extends to display its content.

Pod Width

The width of a Pod is determined by the container it is being displayed in. Each Pod container is configured with a number of equally sized columns. The Pod width will dynamically size to fill the width of the column it is placed in.

Tip: When deciding on a layout for your Pod page we recommend that you consider the type of Pods you are adding to the container and how they might be affected by resizing. Many of the predefined Pods are optimally sized for a 3 column layout. Using alternate layouts may distort the content of the Pods and visually this could detract from the page.

Product Pods

A collection of Pods are provided with the product. The Home section of each Application view is pre-configured with a set of Pods appropriate to that Application view (Pods can be shared across Pod pages). The configuration for each Application view can be updated by an administrator.

See the Curam Personal Page Configuration guide for details.

User configuration of Pod Pages

Each Pod page is pre-configured with a set of available Pods and a set of selected Pods which are visible in the container.

An application user can further customize the workspace by...

- adding Pods from the available list by using the customization-console
- removing Pods by using the customization console
- removing Pods by using the close button on the title bar of the Pod
- moving Pods by dragging to a new location in the container
- filtering Pods by using the filter feature (where available).

Each time a user takes one of the actions that are listed above a record of the current configuration of the page is saved. When the page reloads this saved configuration is redisplayed.

Developing new Pods

In addition to reusing the Pods that are provided in the product, an Organization may want to create new Pods. The Pod framework has the ability to create new Pods with custom content. This guide presents examples of how this can be done.

Getting Started

Before creating a Pod you need to create a Page to host it. The page that hosts our Pods needs a Pod container which manages the Pods allowing them to be added/removed/moved and updated.

Creating a page with a Pod container

Starting with a page that is mapped to a section and tab in the application, add a Pod Container to the page by including the PodContainer.vim file as in the following example:

```
<PAGE PAGE_ID="MyPodContainer"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="file://Curam/UIMSchema.xsd"
>

  <CONNECT>
    <SOURCE NAME="CONSTANT" PROPERTY="MyPodContainer" />
    <TARGET NAME="DISPLAY" PROPERTY="pageID$pageID" />
  </CONNECT>

  <INCLUDE FILE_NAME="PodContainer.vim" />

</PAGE>
```

Related concepts

[Cúram Web Client Reference](#)

Identifying a Pod page

Add a Constant.properties file to the same folder as the UIM file. Add a property to the file that maps to the name of the constant used in the UIM to the *page-id* of the UIM page. When the server interface is called this value is used to uniquely identify the Pod page.

Constant.properties

```
MyPodContainer=MyPodContainer
```

Configuring the database information about the page

The Pod page requires 2 database records to operate. The PAGECONFIG table stores information about which Pods are available on the page. The USERPAGECONFIG table stores the users customizations.

Add the following DMX files to the component and run the database build target to insert the records:

```
<?xml version="1.0" encoding="UTF-8"?>
<table name="PAGECONFIG">
  <column name="pageConfigID" type="id"/>
  <column name="userRoleName" type="text"/>
  <column name="pageID" type="text"/>
  <column name="config" type="text"/>
  <column name="versionNo" type="number"/>

  <row>
    <attribute name="pageConfigID">
      <value>9999</value>
    </attribute>
    <attribute name="userRoleName">
      <value></value>
    </attribute>
    <attribute name="pageID">
      <value>MyPodContainer</value>
    </attribute>
  </row>
</table>
```

```

<attribute name="config">
  <value>
    &lt;page-config&gt;
    &lt;contexts&gt;
    &lt;sequence domain="CURAM_CONTEXT"/&gt;
    &lt;/contexts&gt;
    &lt;availablePods&gt;
    &lt;sequence domain="POD_TYPE_SELECT"&gt;
    &lt;/sequence&gt;
    &lt;/availablePods&gt;
    &lt;layout&gt;
    &lt;sequence domain="COL_SIZE"&gt;
    &lt;value&gt;33&lt;/value&gt;
    &lt;value&gt;33&lt;/value&gt;
    &lt;value&gt;33&lt;/value&gt;
    &lt;/sequence&gt;
    &lt;/layout&gt;&lt;/page-config&gt;
  </value>
</attribute>
<attribute name="versionNo">
  <value>1</value>
</attribute>
</row>
</table>

```

USERPAGECONFIG.DMX

```

<?xml version="1.0" encoding="UTF-8"?>
<table name="USERPAGECONFIG">
  <column name="userPageConfigID" type="id"/>
  <column name="userRoleName" type="text"/>
  <column name="userName" type="text"/>
  <column name="pageID" type="text"/>
  <column name="config" type="text"/>
  <column name="defaultInd" type="bool"/>
  <column name="versionNo" type="number"/>
  <row>
    <attribute name="userPageConfigID">
      <value>9999</value>
    </attribute>
    <attribute name="userRoleName">
      <value></value>
    </attribute>
    <attribute name="userName">
      <value/>
    </attribute>
    <attribute name="pageID">
      <value>MyPodContainer</value>
    </attribute>
    <attribute name="config">
      <value>
        &lt;user-page-config&gt;&lt;/user-page-config&gt;
      </value>
    </attribute>
    <attribute name="defaultInd">
      <value>1</value>
    </attribute>
    <attribute name="versionNo">
      <value>1</value>
    </attribute>
  </row>
</table>

```

Testing the page

Build the application, launch it, login and go to the new Pod Page.

When the new Pod page loads it is empty except for few buttons in the top right corner. The container is empty because you did not add any Pods to the page. Clicking the Customize button opens the customization-console. When the console opens it is empty except for the action buttons. Again, because you do not assign any Pods to the container there are no Pods to select.

- The *Save* button stores the current users customizations.
- The *Reset* button deletes the current users customizations and revert to the default for this Page.
- The *Cancel* button resets the selection in the customization-console and closes it.

In the next section you create a simple Pod and add it to the container.

Hello World Pod

In this section, you are going to create a basic Pod with a title and some text. You also use the Admin Wizard to add the new Pod to the Pod page.

There are 4 basic steps to get the Pod on a page...

1. Declaring a Pod
2. Declaring a PodLoader
3. Implementing a PodLoader
4. Adding the Pod to the Pod Container

Declaring a new Pod

The first step is to declare a new Pod. The PodType is used for this purpose. Create a file CT_PodType.ctx in the component. Add a code and value for the new Pod like the following example. The convention is to use the prefix *PT* for the value. The description field is used by the Administration wizard to refer to the Pod.

Example CT_PodType.ctx, declaring a 'Pod-Type':

```
<?xml version="1.0" encoding="UTF-8"?>
<codetables package="curam.codetable">
  <codetable java_identifier="PODTYPE" name="PodType">
    <code
      default="false"
      java_identifier="HELLOWORLD"
      status="ENABLED"
      value="PT9001"
    >
      <locale language="en" sort_order="0">
        <description>Hello World!</description>
        <annotation/>
      </locale>
    </code>
  </codetable>
</codetables>
```

Related reference

[Sample: The movies DB: A Java class serving our favorite movies](#)

Declaring a new PodLoader

Next, you need to declare the PodLoader. The PodLoader is the java class that generates the fragment of XML that will populate the Pod. The CT_PodLoaderBindings.ctx codetable entry binds a Pod-Type to a PodLoader. When the infrastructure processes the Pod, it looks up the PodLoader class in this codetable.

- The *value* field must match the value field on the PodType codetable. This is what binds the 2 codetable entries.
- The *description* field contains the fully qualified name of the PodLoader class.

CT_PodLoaderBindings.ctx, declaring a 'PodLoader':

```
<?xml version="1.0" encoding="UTF-8"?>
<codetables package="curam.codetable">
  <codetable
    java_identifier="PODLOADERBINDINGS"
    name="PodLoaderBindings"
  >
    <code
      default="false"
      java_identifier="HELLOWORLD"
      status="ENABLED"
      value="PT9001"
    >
  </code>
</codetable>
</codetables>
```

```

    <locale language="en" sort_order="0">
      <description>pods.podloaders.HelloWorld</description>
      <annotation/>
    </locale>
  </code>
</codetable>
</codetables>

```

Now that you added the codetable entries to the PodType and PodLoaderBindings files you need to run the **ctgen** target to create the codetables and the **database** target to insert the codetable values into the database.

Related reference

[Sample: Hello World Pod-Loader](#)

Creating a Pod using a PodLoader

The next step is to create the PodLoader class. The PodLoader extends the class `curam.cefwidgets.pods.pod.impl.PodLoader` and implements the `createPod` method. Create a new class on the Server by copying this example into a class named `HelloWorld` in the package `pods.loaders`.

A very simple PodLoader:

```

001 package pods.podloaders;
002
003 import java.util.Map;
004 import org.w3c.dom.Document;
005 import org.w3c.dom.Node;
006 import curam.cefwidgets.docbuilder.impl.PodBuilder;
007 import curam.cefwidgets.pods.pod.impl.PodLoader;
008 import curam.codetable.PODTYPE;
009
010 public class HelloWorld extends PodLoader {
011
012     @Override
013     public Node createPod(Document document, Map<String,Object> contexts) {
014         try{
015             PodBuilder helloWorld =
016                 PodBuilder.newPod(document, PODTYPE.HELLOWORLD);
017             helloWorld.setTitle("Hello World");
018             return helloWorld.getWidgetRootNode();
019         }catch(Exception e){
020             throw new RuntimeException(e);
021         }
022     }
023 }

```

Input:

The `createPod` method receives 2 parameters from the infrastructure that calls it.

Table 3. createPod method parameters	
Parameter	Description
document	The Document parameter is an instance of a <code>org.w3c.Document</code> class. It is passed to the method by the infrastructure that calls it. The Document instance is used to create and append the 'pod' Node that describes the Pod.
context	The context parameter is used to pass page level parameters to the Pods. Currently this is not supported.

Output:

An instance of the `org.w3c.Node` object is returned by the `createPod` method.

Table 4. Return object from createPod	
Return object	Description
org.w3cNode	The content of the Node that is returned must match a predefined schema. The PodBuilder class provides an API to create a 'pod' Node in the correct format.

In the example above, the simple Pod is created by creating a new instance of a PodBuilder class on line 16. The Document instance from the PodLoader and the codetable value from the PodType codetable are passed to the constructor. On line 17 we use the PodBuilder to set the title of the Pod. The PodBuilder builds a Node tree representing the Pod which is returned on line 18 as a Node object.

Adding a Pod to the Pod Container

The last piece of the jigsaw is adding the Pod to the Pod-Container. You use the wizard provided in the Administrator application. You must login to the Administrator application, so you need the username and password assigned to this application.

When you have logged in you must open the admin wizard by...

1. Selecting the Administration Workspace section
2. Selecting the User Interface tab
3. Selecting Personalized Pod Pages

When the Personalized Pod Pages tab loads you can see the MyPodContainer page that you created in the list of Personal Pages. Selecting edit opens the wizard for maintaining the Personal Page. The first step lists all the Pods available for selection. In this list you find the Pod 'HelloWorld!'. Finally, select the Pod and click next on the remaining steps saving the record. You have now added the Pod to the Pod Container. Log out of the Administrator application and log into the application that contains the Pod page.

Viewing the Pod

Now lets see the Pod in action. Login to the application and go to the Pod page. When the page loads it is empty except for the buttons in the top right corner. Click the customize button to open the *customization-console*. You can see the Pod listed in the console. Select the checkbox beside the Pod and choose save. The page reloads with the Pod defaulted to the top right corner.

You notice that the Pod contains some text *NO CONTENT* which is a place holder added by the infrastructure when the Pod contains no content. In the next section you create another Pod with some content and take a closer look at the PodBuilder class.

Review

In this section, you completed the following:

- You started by adding the new Pod to the PodType and PodLoaderBindings codetables.
- You then created a PodLoader where you used the PodBuilder class to create a Pod and add the title.
- You used the wizard in the Administrator application to add the new Pod to the PodContainer.
- You used the customization-console to select and view the new Pod.

In the next section you create a new Pod with some more interesting content.

Creating a Pod with a list

In this section you expand on what you did in the previous section by adding some content to a Pod and you use the tools provided for creating the basic content types.

Use a new Pod which you add to the Pod-Container in the same way you added the Hello World! Pod in the previous section. You use a movies theme for the examples, so now you can create a Pod with a short list of your favourite movies.

Creating a new list Pod

Register new Pod

In the same way you did in the previous section you are going to register a new Pod and bind it to a PodLoader by adding the codetable entries in the PodType and PodLoaderBindings tables by using the examples shown here.

Example 1: Adding a new PodType to CT_PodType.ctx

```
<code
  default="false"
  java_idenfier="MYFAVMOVIES"
  status="ENABLED"
  value="PT9002"
>
  <locale language="en" sort_order="0">
    <description>My Favourite Movies</description>
    <annotation/>
  </locale>
</code>
```

Example 2: Adding PodLoader binding

```
<code
  default="false"
  java_idenfier="MYFAVMOVIES"
  status="ENABLED"
  value="PT9002"
>
  <locale language="en" sort_order="0" >
    <description>pods.podloaders.MyFavouriteMovies</description>
    <annotation/>
  </locale>
</code>
```

Create a new PodLoader

Next, you add the PodLoader class to your loaders package remembering to reference the new codetable value you created in the *PodType* codetable when you construct the new Pod by using the PodBuilder.

Creating a PodLoader class:

```
001 package pods.podloaders;
002
003 import java.util.Map;
004 import org.w3c.dom.Document;
005 import org.w3c.dom.Node;
006 import curam.cefwidgets.docbuilder.impl.PodBuilder;
007 import curam.cefwidgets.pods.pod.impl.PodLoader;
008 import curam.codetable.PODTYPE;
009
010 public class MyFavouriteMovies extends PodLoader {
011
012     @Override
013     public Node createPod(Document document, Map<String, Object> contexts) {
014         try {
015             PodBuilder moviesPod =
016                 PodBuilder.newPod(document, PODTYPE.MYFAVMOVIES);
017             moviesPod.setTitle("My Favourite Movies");
018             return moviesPod.getWidgetRootNode();
019         } catch (Exception e) {
020             throw new RuntimeException(e);
021         }
022     }
023 }
```

Log into the Administrator application and add the new Pod to the Pod-Container in the same way you did in the previous section.

Open the Pod page and ensure that the Pod is visible.

Create the list

Now that you have a Pod in place you can add content to it. The `PodBuilder` class provides an `addContent(...)` method to add the content to a Pod. In the movies example you are going to delegate to the list widget which can generate a HTML *table*.

To start you need to provide the movies for a list. The related information sample below contains a full program-listing for a Java class that act as a simple read-only DB of your favorite movies. Add this class to a package in the project where it can be accessed by our `PodLoader`.

Next, you create a list in our `PodLoader` and populate it with the favorite movies. In the `PodLoader` add the following code to the `createPod` method before the return statement.

Adding a list to a Pod:

```
001 public Node createPod(Document document, Map<String,Object> contexts) {
002     try{
003         PodBuilder moviesPod =
004             PodBuilder.newPod(document, PODTYPE.MYFAVMOVIES);
005         moviesPod.setTitle("My Favourite Movies");
006
007         MoviesDB moviesDB = new MoviesDB();
008
009         Collection<MoviesDB.Movie> favMovieCollection =
010             moviesDB.getAllMovies();
011         Iterator<MoviesDB.Movie> movieList =
012             favMovieCollection.iterator();
013
014         // Create the list
015         ListBuilder myFavouriteMovies =
016             ListBuilder.createList(1, document);
017
018         int row = 1;
019         while(movieList.hasNext()) {
020             Movie movie = movieList.next();
021             String movieName = movie.title;
022             myFavouriteMovies.addRow();
023             myFavouriteMovies.addEntry(1, row++, movieName);
024         }
025
026         RenderConfig contentRenderer = new RenderConfig(
027             RenderConfigType.STYLE, "single-list");
028         moviesPod.addContent(myFavouriteMovies, contentRenderer);
029
030         return moviesPod.getWidgetRootNode();
031     }catch(Exception e){
032         throw new RuntimeException(e);
033     }
```

Compile your `PodLoader` class and reload the Pod page. The 'My Favourite Movies' Pod are updated with the list of your favourite movies.

In the next section you can look in more detail at how the list was created.

Related reference

[Sample: My favorite movies Pod-Loader](#)

Deconstructing the code

Constructing the list

A Pod does not need to know what its content will be. At run time the Pod delegates to other widgets to produce the HTML that renders the content. Your movies Pod is a list of movie names and it reuses another widget to return a HTML table containing the list data. Like the `PodBuilder` the `ListBuilder` is an API for creating lists that conform to the schema for a renderer called `ListBodyRenderer`. The

ListBuilder generates a fragment of XML that describes a list and at run time the ListBodyRenderer translates this XML into the HTML that can be added to the body of a Pod. To build the Pod content for a Pod the PodLoader use the ListBuilder to produce the list of movies.

The first step in creating a list is to construct a new ListBuilder object. The constructor on line 16 accepts an *int* value which is the number of columns in the list. The second parameter is a *org.w3c.Document*. The document parameter represents the overall PodContainer to which a Pod is added. The document object is used to create the new Nodes that represent a Pod and its content. Those Nodes is appended to some part of the document object.

```
015     ListBuilder myFavouriteMovies =
016         ListBuilder.createList(1, document);
```

Adding rows

Next, iterate over the movies. For each movie you add a new row (line 22).

```
019     while(movieList.hasNext()) {
020         Movie movie = movieList.next();
021         String movieName = movie.title;
022         myFavouriteMovies.addRow();
023         myFavouriteMovies.addEntry(1, row++, movieName);
024     }
```

Creating content in the cells

You use the `addEntry(...)` method to add content to cells. This method accepts a column, a row and a Java Object, which represents the content to be added to the cell.

Table 5. ListBuilder.addEntry(...) parameters		
Parameter	Type	Description
col	int	The column index, offset 1.
row	int	The row index, offset 1.
content	Object<?>	A Java Object that represents the content. The List Renderer can accept a number of different types including CodetableItems and LocalizedString objects which it processes for display. (See Javadoc for ListBuilder)

In the movies Pod you want to add a list of movie names so you pass a Java String in the *content* parameter. On lines 19 to 24 we iterate over the collection of movies.

```
023         myFavouriteMovies.addEntry(1, row++, movieName);
```

Adding the list to a Pod

Now that the list is populated you insert it into the body of the Pod.

The `addContent(...)` method provides the mechanism for adding the Pod content. The method accepts as its first parameter either a *org.w3c.Node* or a *WidgetDocumentBuilder* object (which internally is converted to a Node using the `getWidgetRootNode` operator of the *WidgetDocumentBuilder* object).

The second parameter is a configuration for a Renderer that creates the HTML for our Pod content. The *RendererConfig* object specifies the type of configuration (Style or Domain) and name of a renderer configuration entry. Configuring renderers is covered in detail in the Curam Widget Development Guide.

Table 6. PodBuilder.addContent(...) parameters

param	type	description
content	Node WidgetDocumentBuilder	The Node object is appended to the instance of org.w3c.Document that was passed to the constructor of the PodBuilder.
rendererConfig	RendererConfig	The RendererConfig object nominates the Renderer that processes the <i>content</i> parameter.

```

026     RendererConfig contentRenderer = new RendererConfig(
027         RendererConfigType.STYLE, "single-list");
028     moviesPod.addContent(myFavouriteMovies, contentRenderer);

```

The movies Pod uses the `ListBodyRenderer` which is invoked using a Style configuration called "single-list". On line 28 we add the list widget with the renderer configuration for a list to the body of the Pod.

The Pod is now complete. The content of your movies list is defined in the `ListBuilder` object which is added to the Pod. The `ListBodyRenderer` generates the HTML table which is appended to our Pod body.

Adding a Pod filter

In this section you explore Pod filters. You look at the existing filters available and you use one to add a filter to the movies Pod.

What is a Pod filter?

A Pod can optionally include a Pod filter. The filter allows a user to refine the information that is presented in the Pod. For example, some Pods display reports as charts that are based on periods of time. A Pod filter may present a selection of time periods which the user can select to redraw the Pod with a different chart representing the selected time period.

Types of filter

The `ChoiceRenderer` is a generic renderer for a number of filter style renderers, such as checkboxes, radiobuttons, and dropdowns. The `ChoiceRenderer` delegates to a specific renderer depending on what `displayType` is selected by the `ChoiceBuilder`.

The following table lists the existing filter renderers. The type and `displayType` combine to select a specific renderer.

Table 7. Filter Types

Filter	CT*	Type	Display Type	Renderer
Checkbox	Y	multiple	n/a	CTCheckboxSelectRenderer
Radiobutton	Y	single	n/a	CTRadiobuttonSelectRenderer
Radiobutton	N	db-single	n/a	RadiobuttonSelectRenderer
Dropdown	Y	single	dropdown	CTDropdownSelectRenderer
Dropdown	N	single	listdropdown	ListDropDownSelectRenderer

Note: CT *, Denotes a filter based on the values in a specific codetable file.

Adding a Drop Down Filter

To demonstrate the use of filters you can create a filter for our movies Pod. The filter selects movies by genre. As you did in the last section you insert the complete code sample first to see the Pod in action, then you step through the code to see what you did to create the filter.

Replace the original createPod method in the MyFavouriteMovies PodLoader with the version in the Sample: My Favourite Movies Pod-Loader for Pod filter topic in the links provided. Compile the PodLoader and start the Application.

When the page loads the Pod is updated to include a filter feature denoted by the pen icon on the title bar.

Open the filter by clicking on the pen icon. Select a genre from the drop-down. Use the Save button to save the selection and reload the list. The list only returns movies that match the selected genre in the dropdown.

Lets look at the steps you took to create the filter.

Related reference

[Sample: My Favourite Movies Pod-Loader for Pod filter](#)

[Sample: Hello World Pod-Loader](#)

Creating the Pod Filter

To add a filter to the Pod, you need to use the `PodBuilder.addFilter(...)` method which accepts a parameter of type `PodFilter`. The `PodFilter` object specifies the id of the filter and the renderer configuration that is used to invoke the render that creates the filter.

In our example you are creating a filter with the id "genre" and we are using a renderer called the `ChoiceRenderer` to render the content of the filter.

Creating the Pod Filter

```
010     RendererConfig filterRenderer =
011         new RendererConfig(RendererConfigType.DOMAIN, "CT_CHOICE");
012
013     // Create the PodFilter
014     PodFilter genreFilter =
015         new PodFilter("genre", document, filterRenderer);
```

On line 10-11 you create a renderer configuration which is mapped to a domain 'CT_CHOICE'. This configuration invokes a renderer called `ChoiceRenderer`. You then create a `PodFilter` object passing an id, the document instance of the PodLoader and the renderer configuration.

Creating the options

Now that you have the basic framework of a filter you need to add the choices. The filter can be described as a set of options and a set of selections, which are a subset of the options. Collectively you refer to these as the 'choices'. As you are using the `ChoiceRenderer` to create the drop-down list, so you can use the `ChoiceBuilder` to create the content that you pass to the `ChoiceRenderer`. The `ChoiceBuilder` accepts a `HashMap` which is the set of id's and values. In this case the values are the list of genres that are displayed in the drop down.

In this simple example you use the lower case version of the value as the id.

Creating the set of Choices for the genre drop-down:

```
018     HashMap<String, String> genres = new HashMap<String, String>();
019     genres.put("all", "- All -");
020     genres.put("horror", "Horror");
021     genres.put("drama", "Drama");
022     genres.put("romance", "Romance");
023     genres.put("comedy", "Comedy");
024     genres.put("action", "Action");
025
026     // Create the options and selections using the ChoiceBuilder.
```

```

027     ChoiceBuilder choices =
028         ChoiceBuilder.newInstance(genres, document);

```

Creating the selections

The next step is adding the selected values. In most cases, you want this to be the last saved selections. You can retrieve these values because they are saved for each filter every time a save action occurs on the container. The `PodLoader` class provides a `getPodFilterById(...)` which returns the selected values for each Pod filter.

Retrieving the saved selections and adding them to the Pod filter:

```

031     Node genreSelectionNode =
032         getPodFilterById(PODTYPE.MYFAVMOVIES, "genre", document);
033
034     // Convert the Node to an ArrayList.
035     ArrayList<String> selectedGenres =
036         PodFilter.convertSelectionsNodeToArrayList(genreSelectionNode);
037
038     // Create a default genre selection.
039     if (selectedGenres.isEmpty()){
040         selectedGenres.add("all");
041     }
042     choices.addSelection(selectedGenres.get(0));

```

On line 32, you use the `getPodFiltersById(...)` method to return the saved selections for the 'genre' filter on the 'MYFAVMOVIES' Pod. The values are returned as a Node object in the raw format that they were encoded and stored as. The `PodFilter.convertSelectionsNodeToArrayList(Node)` utility is used to convert the values into a list of String values. On line 42, you add the selected value, in this case it is the only value that is returned in the array.

Setting the type of filter

In our example, you are using the `ChoiceRenderer` to create a dropdown list. The `ChoiceRenderer` delegates to a specific renderer that depends on what `displayType` is selected by the `ChoiceBuilder`. You are creating a drop down list, which is not based on a codetable, so you selected "listdropdown" for the display type.

Setting the type of filter:

```

043     choices.setTypeOfDisplay("listdropdown");

```

Adding a label and CSS styling

Optionally you can add a label to the filter by passing a `String*` to the `addFilterLabel(...)` method. Custom styling can also be applied to the filter by passing CSS class names to the `addCSSClasses(...)`

Note: * The filter label is configured for localization. The String passed to the `addFilterLabel` method is assumed to be a key in a properties file associated with the Pod. If no property value is returned by the key, the key is used as the label.

Adding a PodFilter to a Pod:

```

048     genreFilter.addFilterLabel("Genre");
049     genreFilter.addCSSClasses("genre-filter");

```

Add the Filter to the Pod

Next, you add the filter to the Pod by passing it to the `PodFilter.addFilter(...)` method.

To add a PodFilter to a Pod:

```

050     moviesPod.addFilter(genreFilter);

```

Filtering your Pod

The final task is to filter the content of the Pod. In the movies example you want to filter out all movies where the genre does not match the currently selected one.

To filter the movies by genre:

```
067         if (selectedGenre.equals(movie.genre)
068             || selectedGenre.equals("all")){
069
070             myFavouriteMovies.addRow();
071             myFavouriteMovies.addEntry(1, row++, movieName);
072         }
```

So that completes the filter. When the Pod is loaded for the first time no value is stored for the filter. Every subsequent save stores the filter value, even if that is an empty String. When the Pod reloads it uses the saved value to filter the list of Movies, and it also passes the stored value back to the filter for display so that you can see what filter is being applied.

Using the PodBuilder, PodFilter and ChoiceBuilder has meant that there was no requirement to create Renderers. The builder classes allow you to reuse existing renderers. There are however occasions where you want to create a custom filter type. In the next section, see how to create a new filter renderer.

Creating new Pod filters

In this section, you are going to create a new filter for a Pod to demonstrate how to add form items to Pods.

To complete this section you need to create a Renderer so you need to be familiar with building Renderers and topics such as source paths, target paths andmarshallers. These are covered in the Curam Widget Development Guide. This section assumes you have a good working knowledge of the renderers.

Start with some simple definitions which you should already be familiar with from the Curam Widget Development Guide

Renderer

A Java class that generates HTML markup.

Marshaller

A Java class used to access properties of a server interface and pre-processes data retrieved from a field

Source Path

A pointer used when accessing server interface properties.

Target Path

A pointer used for accessing the content of form fields.

In this example you create a simple text filter that filters by movie title. To create a new filter you are going to...

- Create a Pod filter Renderer
 - Map the source path
 - Map the target path
 - Create the text box
- Create a configuration for the Pod filter Renderer.
- Update our movies PodLoader.
 - Create a new PodFilter that uses our new filter Renderer.

Create a Pod filter Renderer

The related information contains a program listing for a `PodTextFilterRenderer`. Add this class to your component in the webclient project in a package that is named `sample` under the `javasource` folder.

Below we step through the important code.

Related reference

[Sample: PodTextFilterRenderer for new Pod filter example](#)

Preparing to delegate

You start our Renderer by creating a `FieldBuilder`. You do this because our Renderer is not going to do all the work. It delegates the task of rendering the input box to an existing Renderer. The `FieldBuilder` stores up the settings that you pass to that Renderer.

Setting up a `FieldBuilder`

```
025     Field field = ((Field)component);
026
027     final FieldBuilder fieldBuilder =
028         ComponentBuilderFactory.createFieldBuilder();
029     fieldBuilder.copy(field);
```

Setting a source path

In the following code extract, you extend the source path received to access the text for the filter. The text is stored in a Document Node named *text-filter* (you create that later in the `PodLoader`). You use the data accessor to retrieve the text that is added to the input box.

Setting the source path

```
032     String sourcePathExt = "text-filter";
033     Path sourcePath =
034         field.getBinding().getSourcePath().extendPath(sourcePathExt);
035     fieldBuilder.setSourcePath(sourcePath);
```

Setting a target path

Next, you extend the target path. You need to extend the target path to ensure the form item value is processed by the Marshaller attached to the Pod-Container. The Marshaller is configured to process a number of specific target paths. The following example shows how to extend the target path in the correct format.

To set the target path:

```
038     String targetPathExt =
039         "choice/" + field.getID() + "/selected-options";
040     Path targetPath =
041         field.getBinding().getTargetPath().extendPath(targetPathExt);
042     fieldBuilder.setTargetPath(targetPath);
```

Note: The `PodFiltersRenderer` passes an `Id` value to the Renderer it invokes. The `Id` is the concatenation of a *podID* and *filterID* in the format *podID/filterID*. The *Id* value is retrieved by the called renderer using the `getID()` method. That renderer uses the *Id* to uniquely identify itself.

Format of a Pod filter target path

```
choice/ podId
      /
      filterId
      /selected-options
      /option-value
      |--1--|
      --2--|
      ---3---|
```

```
-----4-----/
-----5-----/
```

The extended target path is broken in to what are known as steps which are divided by the '/' character. Each step in our target path is defined here.

Table 8. Target Path break down	
Step	Description
1	This acts as the marker for the marshal. The 'choice' text indicates that this field is to be processed by the Pod-Container.
2	Contains the unique identifier (as specified in the PodType codetable) for the Pod to which the filter is attached. For example, PT9001
3	Contains the unique identifier for the filter attached to the Pod. This Id is created when the PodFilter is constructed in the PodLoader.
4	The <i>selected-options</i> step indicates that this is a filter. Knowing this, the infrastructure processes the form values as a Pod filter.
5	The <i>option-value</i> step is optional and is used to uniquely identify selections in multi-select filters. For example, a checkbox filter can select more than 1 value, so each option gets an <i>option-value</i> step to distinguish it from its siblings.

In our code extract, you extended the target path using the id passed from the PodFiltersRenderer to map our text input form item. At runtime its value will be...

Format of a target path for My Favourite Movies Pod text filter

```
choice/PT9001/title/selections
```

Creating the input field

The last section of the renderer creates the input field.

It actually delegates the task to an existing Renderer which can create the input field. The TextRenderer is mapped to the *TEXT_NODE* Domain, so you simply set the Domain on our FieldBuilder instance and call the render function on that. The TextRenderer creates the form item and returns the input box which is appended to the HTML document.

Rendering the input box

```
045     fieldBuilder.setDomain(context.getDomain("TEXT_NODE"));
046     DocumentFragment textFilter =
047         fragment.getOwnerDocument().createDocumentFragment();
048     context.render(fieldBuilder.getComponent(), fragment, contract);
049
050     fragment.appendChild(textFilter);
```

Create a configuration for the Pod filter Renderer

In the StylesConfig.xml in your component, add the following entry. The 'style' name is used in the PodLoader to configure the PodFilter to use a new PodTextFilterRenderer.

You need to execute the build target for the client to add this configuration.

Style configuration for Pod filter Renderer:

```
<sc:style name="pod-text-filter">
  <sc:plug-in
    class="sample.PodTextFilterRenderer"
    name="component-renderer"
  />
</sc:style>
```

Create a new PodFilter in the PodLoader

After creating a filter, all that remains is to start it in the PodLoader and use the saved value to filter the list of Movies. The related information contains the updated version of the `createPod(...)` method.

The code extract here shows the specific code that creates the text filter and adds it to the Pod.

Adding the Pod Text filter:

```
009 // Create the configuration for the filter renderer.
010 RendererConfig titleFilterRenderer =
011     new RendererConfig(RendererConfigType.STYLE, "pod-text-filter");
012
013 // Create the filter.
014 PodFilter titleFilter =
015     new PodFilter("title", document, titleFilterRenderer);
016 titleFilter.addFilterLabel("Title");
017
018 // Retrieve the saved filter value and extract to an array
019 Node titleTextNode =
020     getPodFilterById(PODTYPE.MYFAVMOVIES, "title", document);
021 ArrayList<String> titleTextArray =
022     PodFilter.convertSelectionsNodeToArrayList(titleTextNode);
023
024 // Create the Node that the filter Renderer expects and add the
025 // saved filter text to it.
026 String titleFilterText = "";
027 if (!titleTextArray.isEmpty()) {
028     titleFilterText = titleTextArray.get(0);
029 }
030 Element titleFilterNode = document.createElement("text-filter");
031 titleTextNode = document.createTextNode(titleFilterText);
032 titleFilterNode.appendChild(titleTextNode);
033 titleFilter.addFilter(titleFilterNode);
034
035 // Add the title filter to the Pod
036 moviesPod.addFilter(titleFilter);
```

Create a new filter:

In lines 10-11, create the configuration for the new filter by referencing the style that was created in the `StylesConfig.xml`. You pass this to the `PodFilter` constructor along with the id of the filter, 'title' in this case.

Retrieve saved filter values:

In lines 19-22, use the utility functions to return the saved values for the 'title' filter and convert them to an array for ease of use.

Create input to Renderer:

In lines 19-33, create the text Node that is passed to our Renderer. The Renderer is expecting a Node named "text-filter" so you create this and add the filter text to it. You add the Node to our `PodFilter` object using the `addFilter(...)` method.

Add the filter to the Pod:

Finally, pass the `PodFilter` object to the `addFilter(...)` method of our `PodBuilder` object.

When you iterate over the movies, you only select movies whose title contains the substring that was returned from the filter. When you put it all together you can load the Pod, select the pen icon to open the filter, choose a genre and click save. The page redraws with the new filtered list.

[Sample: My Favorite Movies Pod-Loader for new Pod filter](#)

Localization in Pods

In this section you are going to look at building Pods in a localizable manner. The examples that are provided use non-locale-specific properties file, these can be supplemented with locale-specific versions to return translated text if required. The Curam Widget Development Guide has a Chapter on

Internationalization and Localization for widgets which covers this topic in more detail and the Curam Regionalization Guide discusses building a locale aware product.

To demonstrate the features built into the framework of Pods to support localization we will update our movies Pod to source various fields from property resources.

The textresource property

For each of the existing renderers that are used with Pods a 'textresource' attribute can be set that defines a resource property file. The code extract in the example shows a renderer reading a property from a text resource file. The file name is passed in the XML received by the renderer. (Refer to the example).

A Renderer reading a property from a text resource file:

```
private static final String RESOURCE_FILE_PATH = "@textresource";
...
String textResource = context.getDataAccessor().get(
    field.getBinding().getSourcePath().extendPath(
        RESOURCE_FILE_PATH));
Path textPath =
    ClientPaths.GENERAL_RESOURCES_PATH.extendPath(textResource);
...
final String saveButtonText =
    context.getDataAccessor().get(
        textPath.extendPath("button.save.text"));
```

In the example above the Renderer is expecting to receive the name of the text resource file in the 'textresource' attribute of the document Node it receives.

Example of a document Node input to a Pod renderer

```
<pod textresource="sample.i18n.MyFavouriteMovies" ...>
  <config>
    ...
  </config>
  <data>
    ...
  </data>
</pod>
```

The Renderer uses the ClientPaths class to create a pointer to the text resource file. The value of the property is retrieved by extending the path into the file to point at the specific property. The path extension is the property key. The value that is returned is the property value. If the request is made for a specific locale, and the resource file for that locale is provided then ClientPaths class accesses the property in the appropriate resource file.

MyFavouriteMovies.properties

```
pod.title=My Favourite Movies
pod.filter.genre.label=Genre
....
```

The location of the properties file must be on the classpath of the client project. Adding the properties file to the javasource folder achieves this. The convention is to add property files to a folder called i18n to differentiate them.

Setting the text resource

A number of Renderers for producing standard content types in Pods are provided. Each of these Renderers has an associated Builder class that acts as an API for the Renderer to simplify the task of generating content to pass to the Renderer.

Table 9. Builders & Renderers	
Builder	Renderer
PodBuilder	PodBodyRenderer
ListBuilder	ListBodyRenderer
PodListBuilder	PodListBodyRenderer
LinkBuilder	LinkRenderer
PodBuilder	PodBodyRenderer

The builder classes provide a `setTextResource(String)` method. At run time each instance of the Renderer uses the properties file received in the 'textresource' attribute to retrieve values that can be localized. Refer to the next section.

Localizing the My Favorite Movies Pod

In this section you update the Movies Pod to read the values from properties files instead of using hardcoded Strings. Start with a simple example, localizing the Pod title. You create a properties file with a title property and then update the PodBuilder to reference this property.

Note: The full listing for the createPod method for all examples that follow can be found in the related reference information.

Related reference

[Sample: My Favourite Movies Pod-Loader for localization](#)

Localizing the Pod

Create a new file called `MyFavouriteMovies.properties` in a folder called 'i18n' under the `javasource/sample` folder in the webclient project (If you have not already created that folder you can do so now). In the file add the key `pod.title` with the value 'My Top Movies' which will distinguish it from the current title.

MyFavouriteMovie.properties:

```
pod.title=My Top Movies
```

Update the code used to construct our Pod by setting a text resource and use the property key for the title of the Pod.

MyFavouriteMovies.java, sourcing the Pod title from a properties file

```
005     moviesPod.setTextResource("sample.i18n.MyFavouriteMovies");
006     moviesPod.setTitle("pod.title");
```

Compile the PodLoader class, build the client target and launch the application. When the Pod is loaded you will see the new title "My Top Movies" which has been read from the properties file.

Now we have a localizable Pod title.

Localizing the filter

Next, you add localizable text to the filter labels. The Pod filter is tied to the Pod so it inherits the same resource file that you give to the Pod. In the same way that you did for the Pod title, you use a property key for the labels and add the property value to the properties file.

MyFavouriteMovies.properties:

```
pod.title=My Top Movies
pod.filter.title.label=Movie Title:
pod.filter.genre.label=Select Genre:
```

MyFavouriteMovies.java, by using the properties file for labels

```
017     titleFilter.addFilterLabel("pod.filter.title.label");
078     genreFilter.addFilterLabel("pod.filter.genre.label");
...     ...
```

When you load the Pod you see that the label on the filter is changed to the value specified in the properties file.

Localizing the movie list

Take one more example. This time you use a properties file with a list of movies. To do so, you add a title to the list that is sourced from a properties file.

- Create a new properties file MoviesList.properties and add it to the i18n folder.
- Build the client to publish the properties.
- Update the list to use the properties file and add a column title as a property key. See the example.

Adding a column title

```
091     myFavouriteMovies.setTextResource("sample.i18n.MoviesList");
092     myFavouriteMovies.addColumnTitle(1, "list.col1.title");
```

Sharing properties files

The last example of localizing the list illustrates the value of sharing properties files. If you think about how a Pod is made up of various widgets, the complexity of which might extend to any number of widgets, then having 1 property file per widget would be difficult to maintain. For this reason, it makes sense to share the properties files for aggregated widgets such as Pods even though it is not technically necessary to do so.

In the example here, instead of creating a new properties file for the movies list widget, you can reuse the MyFavouriteMovies.properties file. Using this technique you have a single resource for all properties that are associated with the 'MyFavouriteMovies' Pod.

Sample program listings

This section contains the sample program listings for the My favorite movies pod.

Sample: The movies DB: A Java class serving our favorite movies

This class is the helper for the examples. It is a simple read-only Java DB for our favorite Movies.

```
package pods.podloaders;

import java.util.Collection;
import java.util.TreeMap;

/** Simple read-only Java DB for a movie collection */
public class MoviesDB {
```

```

private TreeMap<Integer, Movie> allMovies;

/** Constructor */
public MoviesDB() {

    allMovies = new TreeMap<Integer, Movie>();
    allMovies.put(1, new MoviesDB.Movie(1,"The Dark Knight", "action",
        2008, "Christopher Nolan", "Christian Bale", 1));
    allMovies.put(2, new MoviesDB.Movie(2,"Casablanca", "romance",
        1942, "Michael Curtiz", "Humphrey Bogart", 3));
    allMovies.put(3, new MoviesDB.Movie(3,"Schindler's List", "drama",
        1993, "Steven Spielberg", "Liam Neeson", 7));
    allMovies.put(4, new MoviesDB.Movie(4,"Alien", "horror",
        1979, "Ridley Scott", "Sigourney Weaver", 1));
    allMovies.put(5, new MoviesDB.Movie(1, "The GodFather, Part II",
        "drama", 1974, "Francis Ford Coppola", "Marlon Brando", 6));
    allMovies.put(5, new MoviesDB.Movie(1, "Toy Story 3",
        "comedy", 2010, "Lee Unkrich", "Tom Hanks", 2));
    allMovies.put(6, new MoviesDB.Movie(6, "Toy Story 2",
        "comedy", 1999, "John Lasseter", "Tom Hanks", 0));

}

/** Return all movies as a Collection */
public Collection<MoviesDB.Movie> getAllMovies(){
    Collection<MoviesDB.Movie> movieCollection =
        this.allMovies.values();
    return movieCollection;
}

/** Return a movie by its Id */
public Movie getMovieById(Integer id) {
    return allMovies.get(id);
}

}

class Movie {

    public int id,year,oscars;
    public String title, genre, director, leadrole, url;

    public Movie(int id,String title,String genre,
        int year,String director,String leadrole, int oscar){

        this.oscars = oscar;
    }

}
}

```

Sample: Hello World Pod-Loader

This is the simplest Pod-Loader you can have

```

001 package pods.podloaders;
002
003 import java.util.Map;
004 import org.w3c.dom.Document;
005 import org.w3c.dom.Node;
006 import curam.cefwidgets.docbuilder.impl.PodBuilder;
007 import curam.cefwidgets.pods.pod.impl.PodLoader;
008 import curam.codetable.PODTYPE;
009
010 public class HelloWorld extends PodLoader {
011
012     @Override
013     public Node createPod(Document document, Map<String,Object> contexts) {
014         try{
015             PodBuilder helloWorld =
016                 PodBuilder.newPod(document, PODTYPE.HELLOWORLD);
017             helloWorld.setTitle("Hello World");
018             return helloWorld.getWidgetRootNode();
019         }catch(Exception e){
020             throw new RuntimeException(e);
021         }
022     }
023 }

```

```
022     }
023 }
```

Sample: My favorite movies Pod-Loader

This version of the createPod method creates a list of movies using the MoviesDB class

```
001 public Node createPod(Document document, Map<String,Object> contexts) {
002     try{
003         PodBuilder moviesPod =
004             PodBuilder.newPod(document, PODTYPE.MYFAVMOVIES);
005         moviesPod.setTitle("My Favourite Movies");
006
007         MoviesDB moviesDB = new MoviesDB();
008
009         Collection<MoviesDB.Movie> favMovieCollection =
010             moviesDB.getAllMovies();
011         Iterator<MoviesDB.Movie> movieList =
012             favMovieCollection.iterator();
013
014         // Create the list
015         ListBuilder myFavouriteMovies =
016             ListBuilder.createList(1, document);
017
018         int row = 1;
019         while(movieList.hasNext()) {
020             Movie movie = movieList.next();
021             String movieName = movie.title;
022             myFavouriteMovies.addRow();
023             myFavouriteMovies.addEntry(1, row++, movieName);
024         }
025
026         RendererConfig contentRenderer = new RendererConfig(
027             RendererConfigType.STYLE, "single-list");
028         moviesPod.addContent(myFavouriteMovies, contentRenderer);
029
030         return moviesPod.getWidgetRootNode();
031     }catch(Exception e){
032         throw new RuntimeException(e);
033     }
}
```

Sample: My Favourite Movies Pod-Loader for Pod filter

This version of the createPod method adds a filter to the Movies Pod.

```
001 public Node createPod(Document document, Map<String,Object> contexts) {
002     try{
003         PodBuilder moviesPod =
004             PodBuilder.newPod(document, PODTYPE.MYFAVMOVIES);
005         moviesPod.setTitle("My Favourite Movies");
006
007         MoviesDB moviesDB = new MoviesDB();
008
009         // Create the configuration for the drop down filter.
010         RendererConfig filterRenderer =
011             new RendererConfig(RendererConfigType.DOMAIN, "CT_CHOICE");
012
013         // Create the PodFilter
014         PodFilter genreFilter =
015             new PodFilter("genre", document, filterRenderer);
016
017         // Create genre list
018         HashMap<String, String> genres = new HashMap<String, String>();
019         genres.put("all", "- All -");
020         genres.put("horror", "Horror");
021         genres.put("drama", "Drama");
022         genres.put("romance", "Romance");
023         genres.put("comedy", "Comedy");
024         genres.put("action", "Action");
025
026         // Create the options and selections using the ChoiceBuilder.
027         ChoiceBuilder choices =
028             ChoiceBuilder.newInstance(genres, document);
029
030         // Return the last saved selection for the filter with id "genre".
031         Node genreSelectionNode =
```

```

032         getPodFilterById(PODTYPE.MYFAVMOVIES, "genre", document);
033
034         // Convert the Node to an ArrayList.
035         ArrayList<String> selectedGenres =
036             PodFilter.convertSelectionsNodeToArrayList(genreSelectionNode);
037
038         // Create a default genre selection.
039         if (selectedGenres.isEmpty()){
040             selectedGenres.add("all");
041         }
042         choices.addSelection(selectedGenres.get(0));
043         choices.setTypeOfDisplay("listdropdown");
044
045         genreFilter.addFilter(choices.getWidgetRootNode());
046
047         // Add a filter label
048         genreFilter.addFilterLabel("Genre");
049         genreFilter.addCSSClasses("genre-filter");
050         moviesPod.addFilter(genreFilter);
051
052
053         Collection<MoviesDB.Movie> favMovieCollection =
054             moviesDB.getAllMovies();
055         Iterator<MoviesDB.Movie> movieList =
056             favMovieCollection.iterator();
057
058         // Create the list
059         ListBuilder myFavouriteMovies =
060             ListBuilder.createList(1, document);
061
062         int row = 1;
063         while(movieList.hasNext()) {
064             Movie movie = movieList.next();
065             String movieName = movie.title;
066             String selectedGenre = selectedGenres.get(0);
067             if (selectedGenre.equals(movie.genre)
068                 || selectedGenre.equals("all")){
069
070                 myFavouriteMovies.addRow();
071                 myFavouriteMovies.addEntry(1, row++, movieName);
072             }
073         }
074
075         RendererConfig contentRenderer = new RendererConfig(
076             RendererConfigType.STYLE, "single-list");
077         moviesPod.addContent(myFavouriteMovies, contentRenderer);
078
079         return moviesPod.getWidgetRootNode();
080     } catch (Exception e) {
081         throw new RuntimeException(e);
082     }
083 }

```

Sample: PodTextFilterRenderer for new Pod filter example

The following renderer creates the text filter that you use to create new filters for Pods:

```

001 package sample;
002
003 import org.w3c.dom.DocumentFragment;
004 import curam.util.client.ClientException;
005 import curam.util.client.model.Component;
006 import curam.util.client.model.ComponentBuilderFactory;
007 import curam.util.client.model.Field;
008 import curam.util.client.model.FieldBuilder;
009 import curam.util.client.view.RendererContext;
010 import curam.util.client.view.RendererContract;
011 import curam.util.common.path.DataAccessException;
012 import curam.util.common.path.Path;
013 import curam.util.common.plugin.PluginException;
014 import curam.widget.render.infrastructure.AbstractComponentRenderer;
015
016 /**
017  * Creates a text input for use with a Pod Filter
018  */
019 public class PodTextFilterRenderer extends AbstractComponentRenderer {
020
021     public void render(Component component, DocumentFragment fragment,
022         RendererContext context, RendererContract contract)

```

```

023     throws ClientException, DataAccessException, PlugInException {
024
025     Field field = ((Field)component);
026
027     final FieldBuilder fieldBuilder =
028         ComponentBuilderFactory.createFieldBuilder();
029     fieldBuilder.copy(field);
030
031     // Update the source path to point at the text node
032     String sourcePathExt = "text-filter";
033     Path sourcePath =
034         field.getBinding().getSourcePath().extendPath(sourcePathExt);
035     fieldBuilder.setSourcePath(sourcePath);
036
037     // Update the target path to use the Pod filter id
038     String targetPathExt =
039         "choice/" + field.getID() + "/selected-options";
040     Path targetPath =
041         field.getBinding().getTargetPath().extendPath(targetPathExt);
042     fieldBuilder.setTargetPath(targetPath);
043
044     // Use TextRenderer to create input box
045     fieldBuilder.setDomain(context.getDomain("TEXT_NODE"));
046     DocumentFragment textFilter =
047         fragment.getOwnerDocument().createDocumentFragment();
048     context.render(fieldBuilder.getComponent(), fragment, contract);
049
050     fragment.appendChild(textFilter);
051 }
052 }

```

Sample: My Favorite Movies Pod-Loader for new Pod filter

This version of the create Pod method includes the creation of the movie title filter

```

001 public Node createPod(Document document, Map<String,Object> contexts) {
002     try{
003         PodBuilder moviesPod =
004             PodBuilder.newPod(document, PODTYPE.MYFAVMOVIES);

INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some jurisdictions do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM websites are provided for convenience only and do not in any manner serve as an endorsement of those websites. The materials at those websites are not part of the materials for this IBM product and use of those websites is at your own risk.

IBM may use or distribute any of the information you provide in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM Director of Licensing IBM Corporation North Castle Drive, MD-NC119 Armonk, NY 10504-1785 US

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this document and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement or any equivalent agreement between us.

The performance data and client examples cited are presented for illustrative purposes only. Actual performance results may vary depending on specific configurations and operating conditions.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

Statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

All IBM prices shown are IBM's suggested retail prices, are current and are subject to change without notice. Dealer prices may vary.

This information is for planning purposes only. The information herein is subject to change before the products described become available.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to actual people or business enterprises is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. The sample programs are provided "AS IS", without warranty of any kind. IBM shall not be liable for any damages arising out of your use of the sample programs.

Privacy Policy considerations

IBM Software products, including software as a service solutions, ("Software Offerings") may use cookies or other technologies to collect product usage information, to help improve the end user experience, to tailor interactions with the end user or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth below.

Depending upon the configurations deployed, this Software Offering may use session cookies or other similar technologies that collect each user's name, user name, password, and/or other personally identifiable information for purposes of session management, authentication, enhanced user usability, single sign-on configuration and/or other usage tracking and/or functional purposes. These cookies or other similar technologies cannot be disabled.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from end users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, see IBM's Privacy Policy at <http://www.ibm.com/privacy> and IBM's Online Privacy Statement at <http://www.ibm.com/privacy/details> the section entitled "Cookies, Web Beacons and Other Technologies" and the "IBM Software Products and Software-as-a-Service Privacy Statement" at <http://www.ibm.com/software/info/product-privacy>.

Trademarks

IBM, the IBM logo, and [ibm.com](http://www.ibm.com) are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Web at "Copyright and trademark information" at <http://www.ibm.com/legal/copytrade.shtml>.

Adobe, the Adobe logo, PostScript, and the PostScript logo are either registered trademarks or trademarks of Adobe Systems Incorporated in the United States, and/or other countries.

Java and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

The registered trademark Linux is used pursuant to a sublicense from the Linux Foundation, the exclusive licensee of Linus Torvalds, owner of the mark on a worldwide basis.

Microsoft, Windows, Windows NT, and the Windows logo are trademarks of Microsoft Corporation in the United States, other countries, or both.

UNIX is a registered trademark of The Open Group in the United States and other countries.

Other names may be trademarks of their respective owners. Other company, product, and service names may be trademarks or service marks of others.
